Dynamic causal modeling (DCM) provides a framework for the analysis of effective connectivity among neuronal subpopulations that subtend invasive (electrocorticograms and local field potentials) and non-invasive (electroencephalography and magnetoencephalography) electrophysiological responses. This paper reviews the suite of neuronal population models including neural masses, fields and conductance-based models that are used in DCM. These models are expressed in terms of sets of differential equations that allow one to model the synaptic underpinnings of connectivity. We describe early developments using neural mass models, where convolution-based dynamics are used to generate responses in laminar-specific populations of excitatory and inhibitory cells. We show that these models, though resting on only two simple transforms, can recapitulate the characteristics of both evoked and spectral responses observed empirically. Using an identical neuronal architecture, we show that a set of conductance based models—that consider the dynamics of specific ion-channels—present a richer space of responses; owing to non-linear interactions between conductances and membrane potentials. We propose that conductance-based models may be more appropriate when spectra present with multiple resonances. Finally, we outline a third class of models, where each neuronal subpopulation is treated as a
in other words, as a manifold on the cortical surface. By explicitly accounting for
propagation of cortical activity through partial differential equations (PDEs),
the topology of connectivity—through local lateral interactions among
may be inferred, even in the absence of spatially resolved data. We also
models allow for a detailed analysis of structure–function relationships
ur review highlights the relationship among these models and how the
sked of empirical data suggests an appropriate model class.

The state of a neuron comprises a number of attributes, membrane potentials, conductances etc. Modelling these states can become intractable. Mean field approximations summarise the states in terms of their ensemble density. **Neural mass models consider only point densities** and describe the interaction of the means in the ensemble

Meso-scale dynamics

Outline

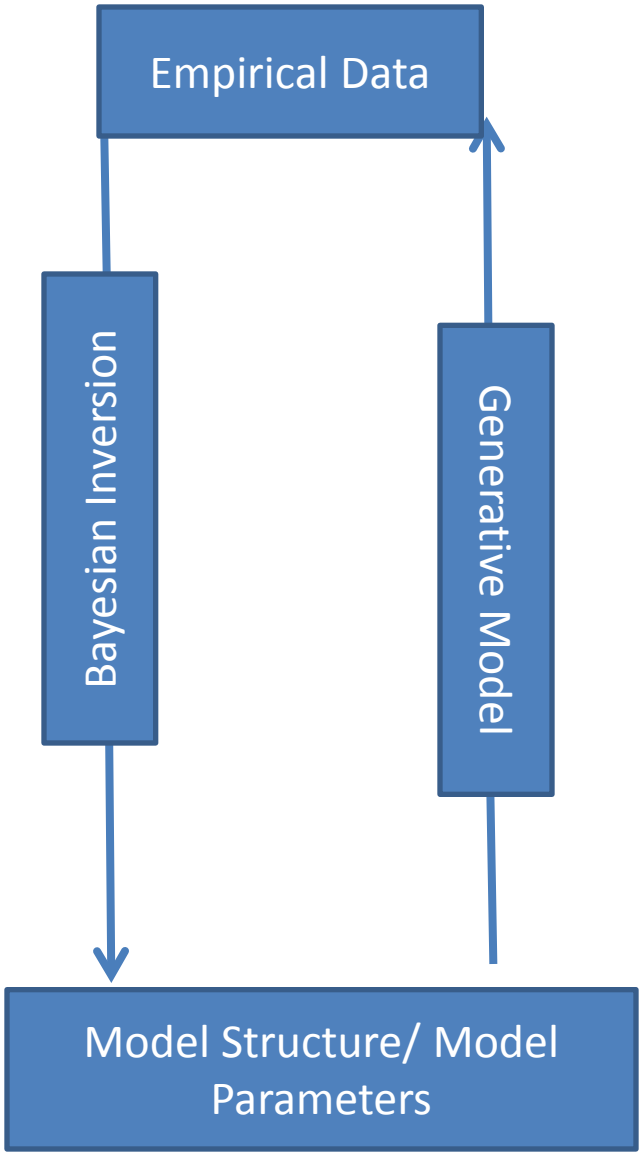
The DCM Approach

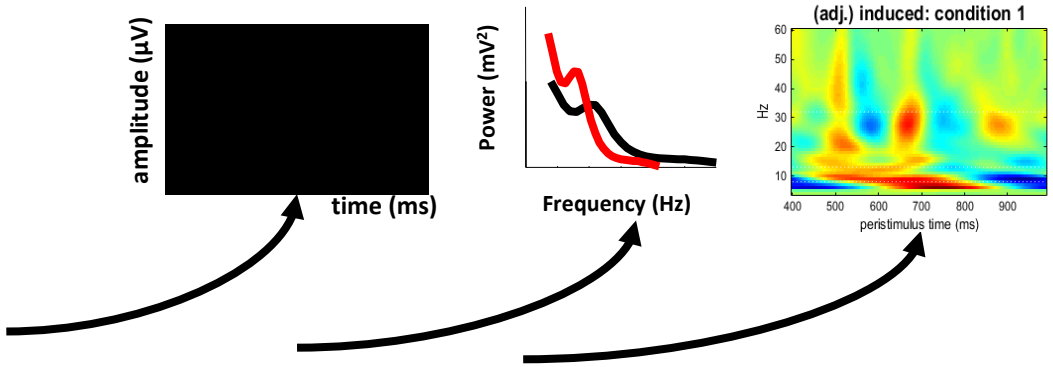
Models of Neural Population Activity

Quantifying the Goodness of Models and Model Parameters

How it works in practice

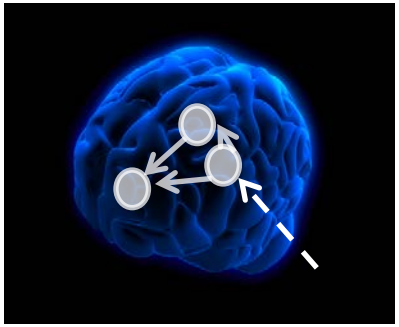
Dynamic Causal Modelling: Inversion Framework



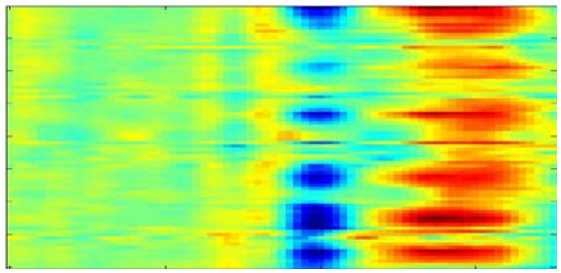


$$\frac{dx}{dt} = F(x,u,\theta)$$

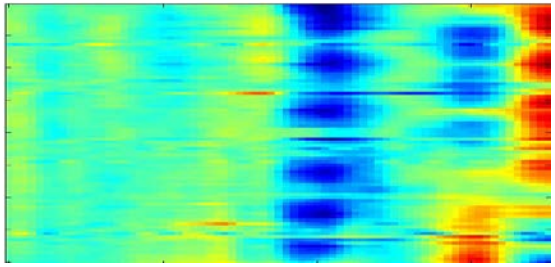
Neural State Equation Can Generate Different Dynamics

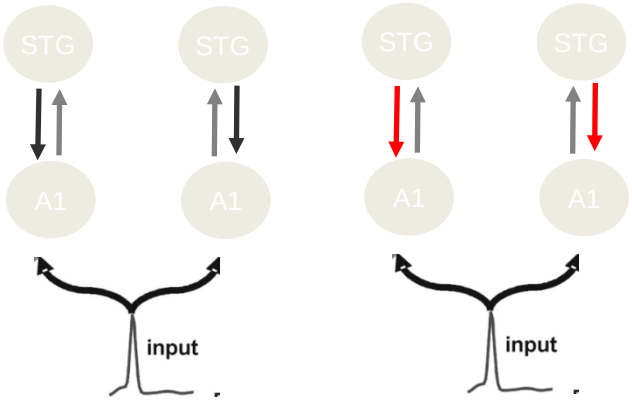


Model Selection & Hypothesis Testing



data *y*





Model *1* → $p(y \mid m_1)$, $p(\theta \mid y, m_1)$

Model *2* → $p(y \mid m_2)$, $p(\theta \mid y, m_2)$

⋮

Model *n* → $p(y \mid m_n)$, $p(\theta \mid y, m_n)$

Model selection: $p(y \mid m_i)$

Bayesian Statistics

new data

prior knowledge

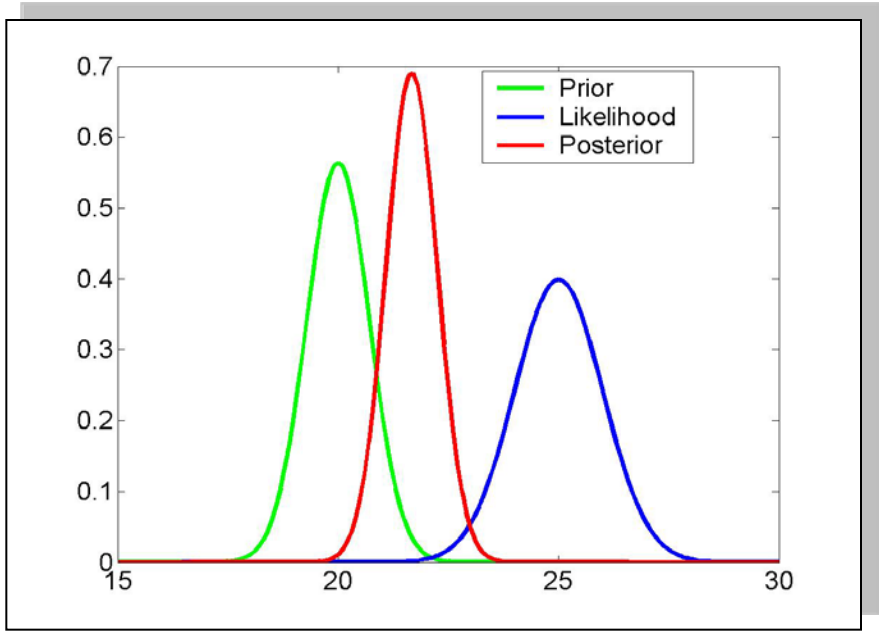
$$p(y \mid \theta) \qquad p(\theta)$$

$$p(\theta \mid y) \propto p(y \mid \theta)\, p(\theta)$$

posterior $\propto$ likelihood • prior

Bayes theorem allows one to formally incorporate prior knowledge into computing statistical probabilities.

In DCM for Neurphysiology priors include time constants, Extrinsic connectivity strengths, PSP, delays etc.



The “posterior” probability of the parameters given the data is an optimal combination of prior knowledge and new data, weighted by their relative precision.

Bayesian Inversion

Neural Parameters:
Dynamic Model

$$\theta = H_e, H_i, \kappa_e, \kappa_i, \kappa_a, \gamma_1, \gamma_2, \gamma_3, \gamma_4, \gamma_{5,} g, A_F, A_B, A_L$$

Observer function:
Forward Spatial Model

$$y = L(\vartheta) x_0$$

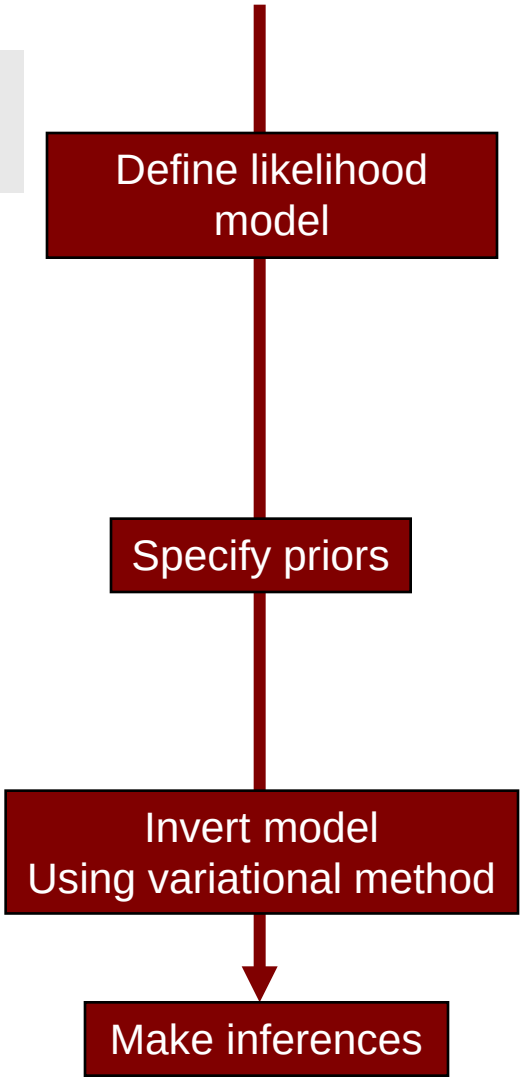
$$p(\theta, m) = N(\mu_\theta, \Sigma_\theta)$$

Inference on models

$$p(y \mid m) = \int p(y \mid \theta, m)\, p(\theta) d\theta$$

Inference on parameters

$$p(\theta \mid y, m) = \frac{p(y \mid \theta, m)\, p(\theta, m)}{p(y \mid m)}$$



VB in a nutshell (mean-field approximation)

Free-energy approximation to model evidence

$$\ln p(y|m) = F + KL\left[q(\theta,\lambda), p(\theta,\lambda|y)\right]$$

$$F = \left\langle \ln p(y,\theta,\lambda)\right\rangle_q - KL\left[q(\theta,\lambda), p(\theta,\lambda|m)\right]$$

Mean Field Partition

$$p(\theta,\lambda|y) \approx q(\theta,\lambda) = q(\theta)q(\lambda)$$

Maximise variational energies via gradient ascent

$$q(\theta) \propto \exp(I_\theta) = \exp\left[\left\langle \ln p(y,\theta,\lambda)\right\rangle_{q(\lambda)}\right]$$

$$q(\lambda) \propto \exp(I_\lambda) = \exp\left[\left\langle \ln p(y,\theta,\lambda)\right\rangle_{q(\theta)}\right]$$

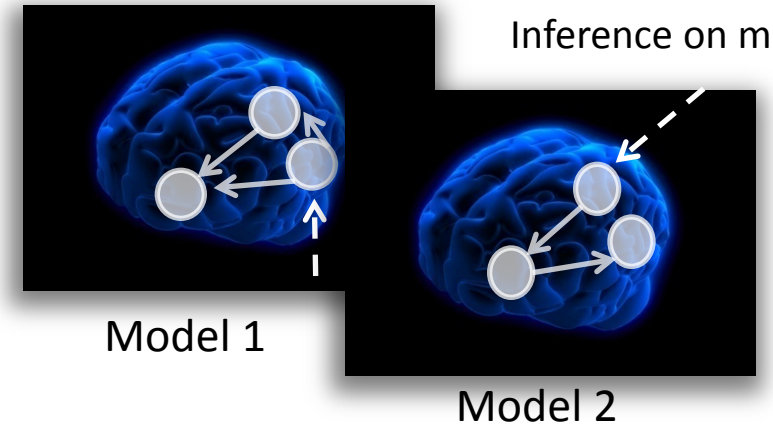
Using Laplace assumption: local covariance is a function of the mean

Dynamic Causal Modelling: Framework

Bayesian Inversion

Bayes' rules: $p(\theta \mid y, m) = \frac{p(y \mid \theta, m)\, p(\theta \mid m)}{p(y \mid m)}$

Free Energy: $F \underset{\max}{=} \ln p(y|m) - KL(q(\theta) \| p(\theta|y, m))$



Inference on models

Model 1

Model 2

Model comparison via Bayes factor:

$$BF = \frac{p(y \mid m_1)}{p(y \mid m_2)}$$

Kass & Raftery 1995, *J. Am. Stat. Assoc.*

B_{12}	$p(m_1\|y)$	Evidence
1 to 3	50-75%	weak
3 to 20	75-95%	positive
20 to 150	95-99%	strong
≥ 150	≥ 99%	Very strong

Dynamic Causal Modelling: Framework

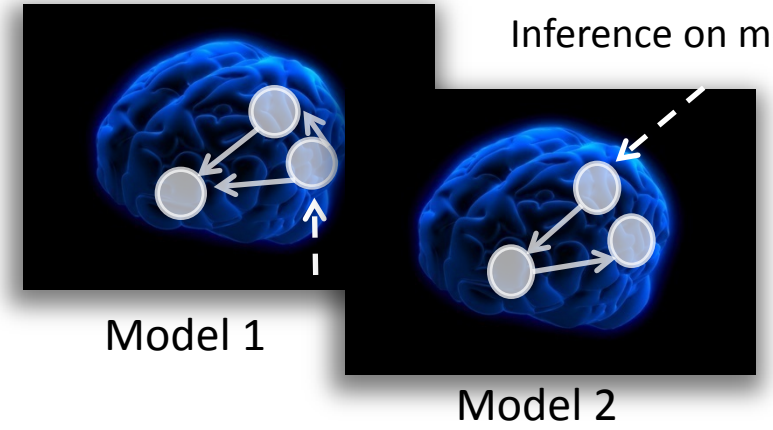
Bayesian Inversion

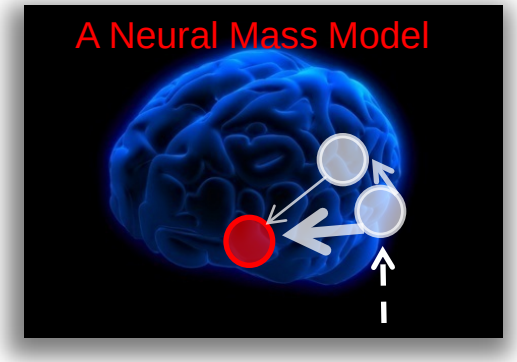
Bayes' rules: $p(\theta \mid y, m) = \dfrac{p(y \mid \theta, m)\, p(\theta \mid m)}{p(y \mid m)}$

Free Energy: $F \underset{\max}{=} \ln p(y|m) - KL(q(\theta) \,|\, p(\theta|y, m))$

Inference on parameters

Inference on models



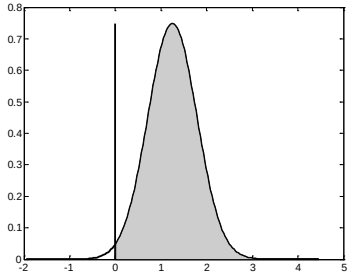


Model 1

Model comparison via Bayes factor:

$$BF = \frac{p(y \mid m_1)}{p(y \mid m_2)}$$

$q(\theta) \approx p(\theta|y, m)$



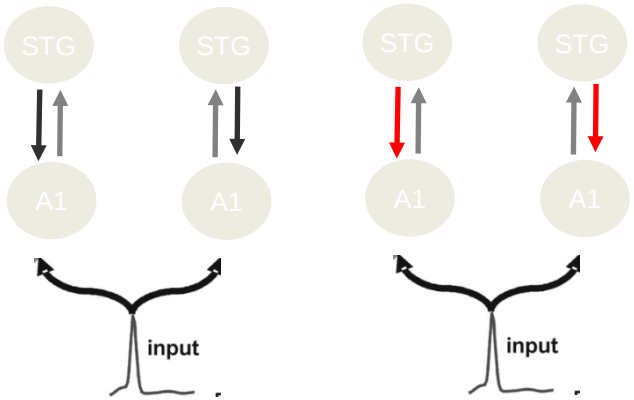
$p(conn > 0 \mid y) = 99.1\%$

Bayesian Model Comparison

The model goodness: Negative Free Energy

$$F = \log p(y \mid m) - KL\left[q(\theta), p(\theta \mid y, m)\right]$$

Accuracy - Complexity



$$KL\left[q(\theta), p(\theta \mid m)\right]$$
$$= \frac{1}{2}\ln\left|C_\theta\right| - \frac{1}{2}\ln\left|C_{\theta|y}\right| + \frac{1}{2}\left(\mu_{\theta|y} - \mu_\theta\right)^T C_\theta^{-1}\left(\mu_{\theta|y} - \mu_\theta\right)$$

The complexity term of *F* is higher

- the more independent the prior parameters (↑ effective DFs)
- the more dependent the posterior parameters
- the more the posterior mean deviates from the prior mean

Summary

1. DCM enables testing hypotheses about how brain sources communicate.
2. DCM is based on a neurobiologically plausible generative model of evoked responses.
3. Differences between conditions are modelled as modulation of connectivity.
4. Inference using Bayesian model selection, Bayesian parameter testing, or mix Bayes and classical stats!
