

Evolution of HIV-1 Across the Within and Between-Host Scales: The Role of Transmission Bottlenecks

SIAM Conference on Applications of Dynamical Systems
MS12 Advances in Infectious Disease Modeling
Sunday May 17th, 2019

Multi-Scale Evolution

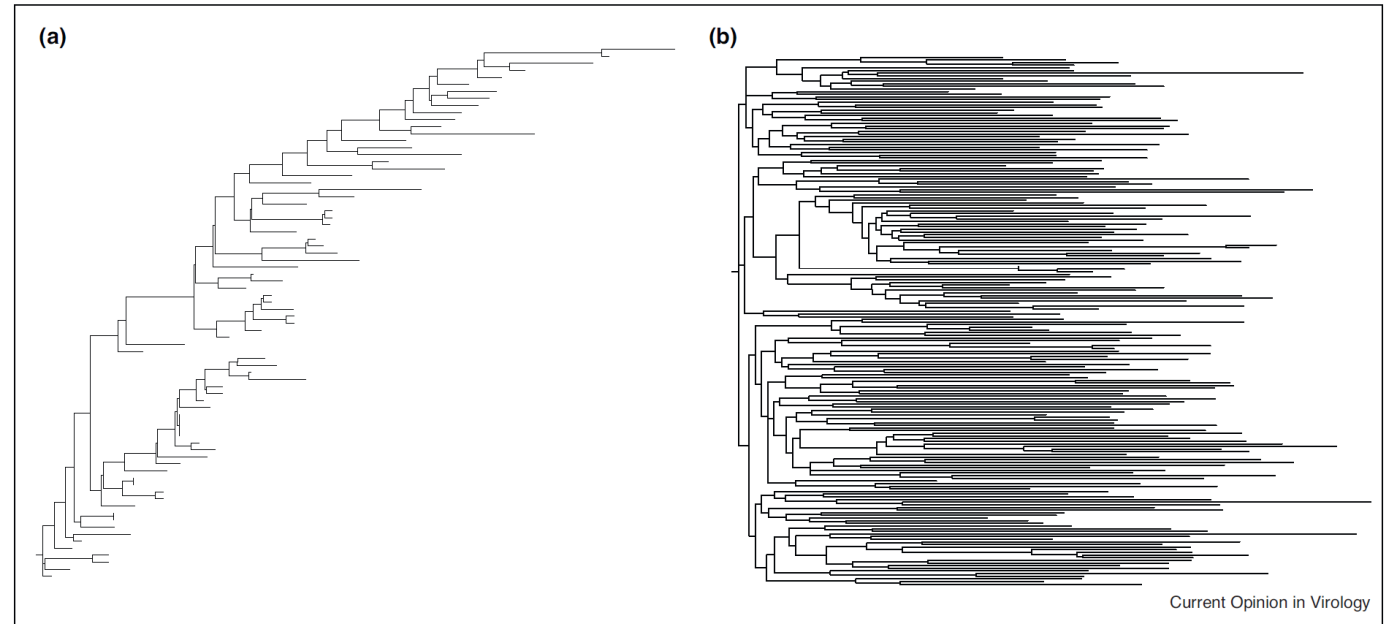

- Within-host
 - HIV-1 is a rapidly replicating retrovirus
 - Estimated 10^8 newly infected cells per day
- Transmission Bottleneck
 - In the majority of cases, new infections are started by a single virus strain
- Between-host
 - 1.8 million new HIV infections in 2017

Multi-Scale Evolution: Transmission Bottleneck

- The rate of evolution of the virus is 2 to 6 times greater within than between hosts.
- A current hypothesis: The HIV-1 latent reservoir acts to archive less-evolved virus for later transmission.
- We offer a complimentary hypothesis: traits for efficiency of transmission, across the bottleneck, are not under direct selection and are thus subject to drift within-host

Theys K., et. al., *The impact of HIV-1 within-host evolution on transmission dynamics*, Current Opinion in Virology Dec; 28:92-101. doi: 10.1016/j.coviro.2017.12.001 (2018)

Multi-Scale Evolution: Insights from Influenza

- Within-host evolution of influenza virus is consistent with a neutral model of evolution
- Uncertainty of the between-host bottleneck size
- Rare variants have a low probability of transmission
- Influenza evolution is dominated by stochasticity on local scales and positive selection on global scales

McCrone J., et. al., *Stochastic processes constrain the within and between host evolution of influenza virus*. 2018;7:e35962. doi: 10.7554/eLife.35962 (2018)

Multi-Scale Evolution: Transmission Bottleneck

Questions

Does allowing transmission fitness to evolve within-host without direct selection pressure have the effect of slowing the observed rate of evolution over epidemic time?

Is the difference between within- and between host evolutionary rates sensitive to the size and composition of the bottleneck Inoculum?

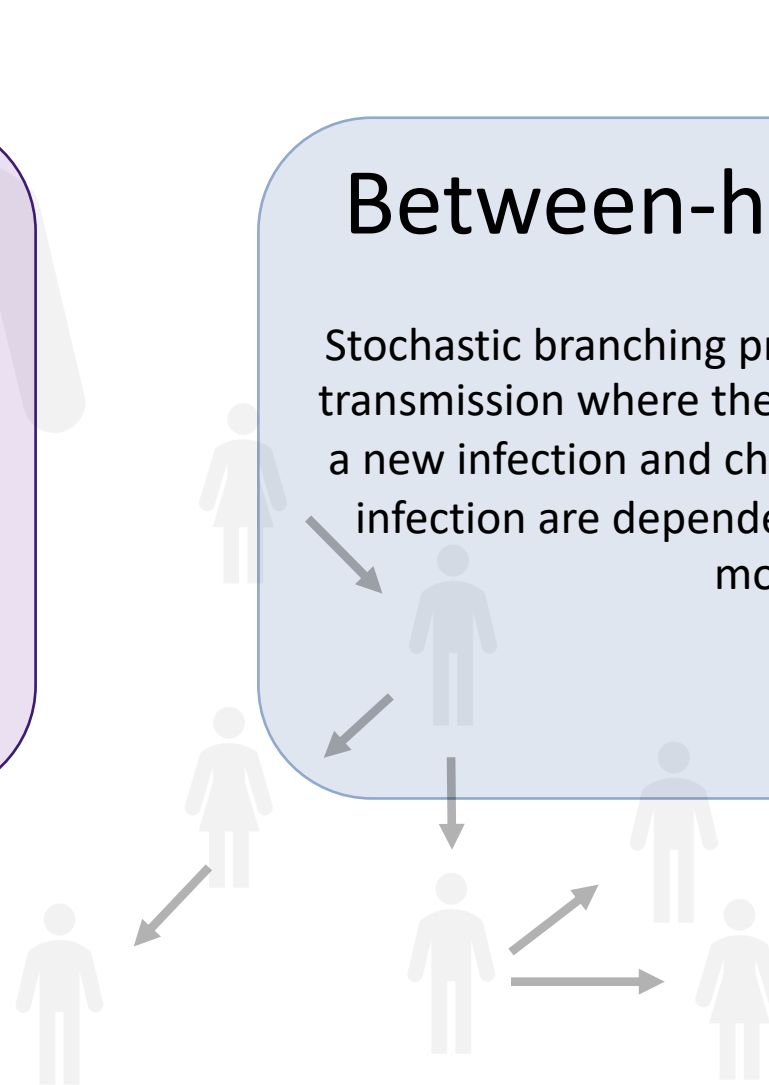

Methods: Overview

Within-host

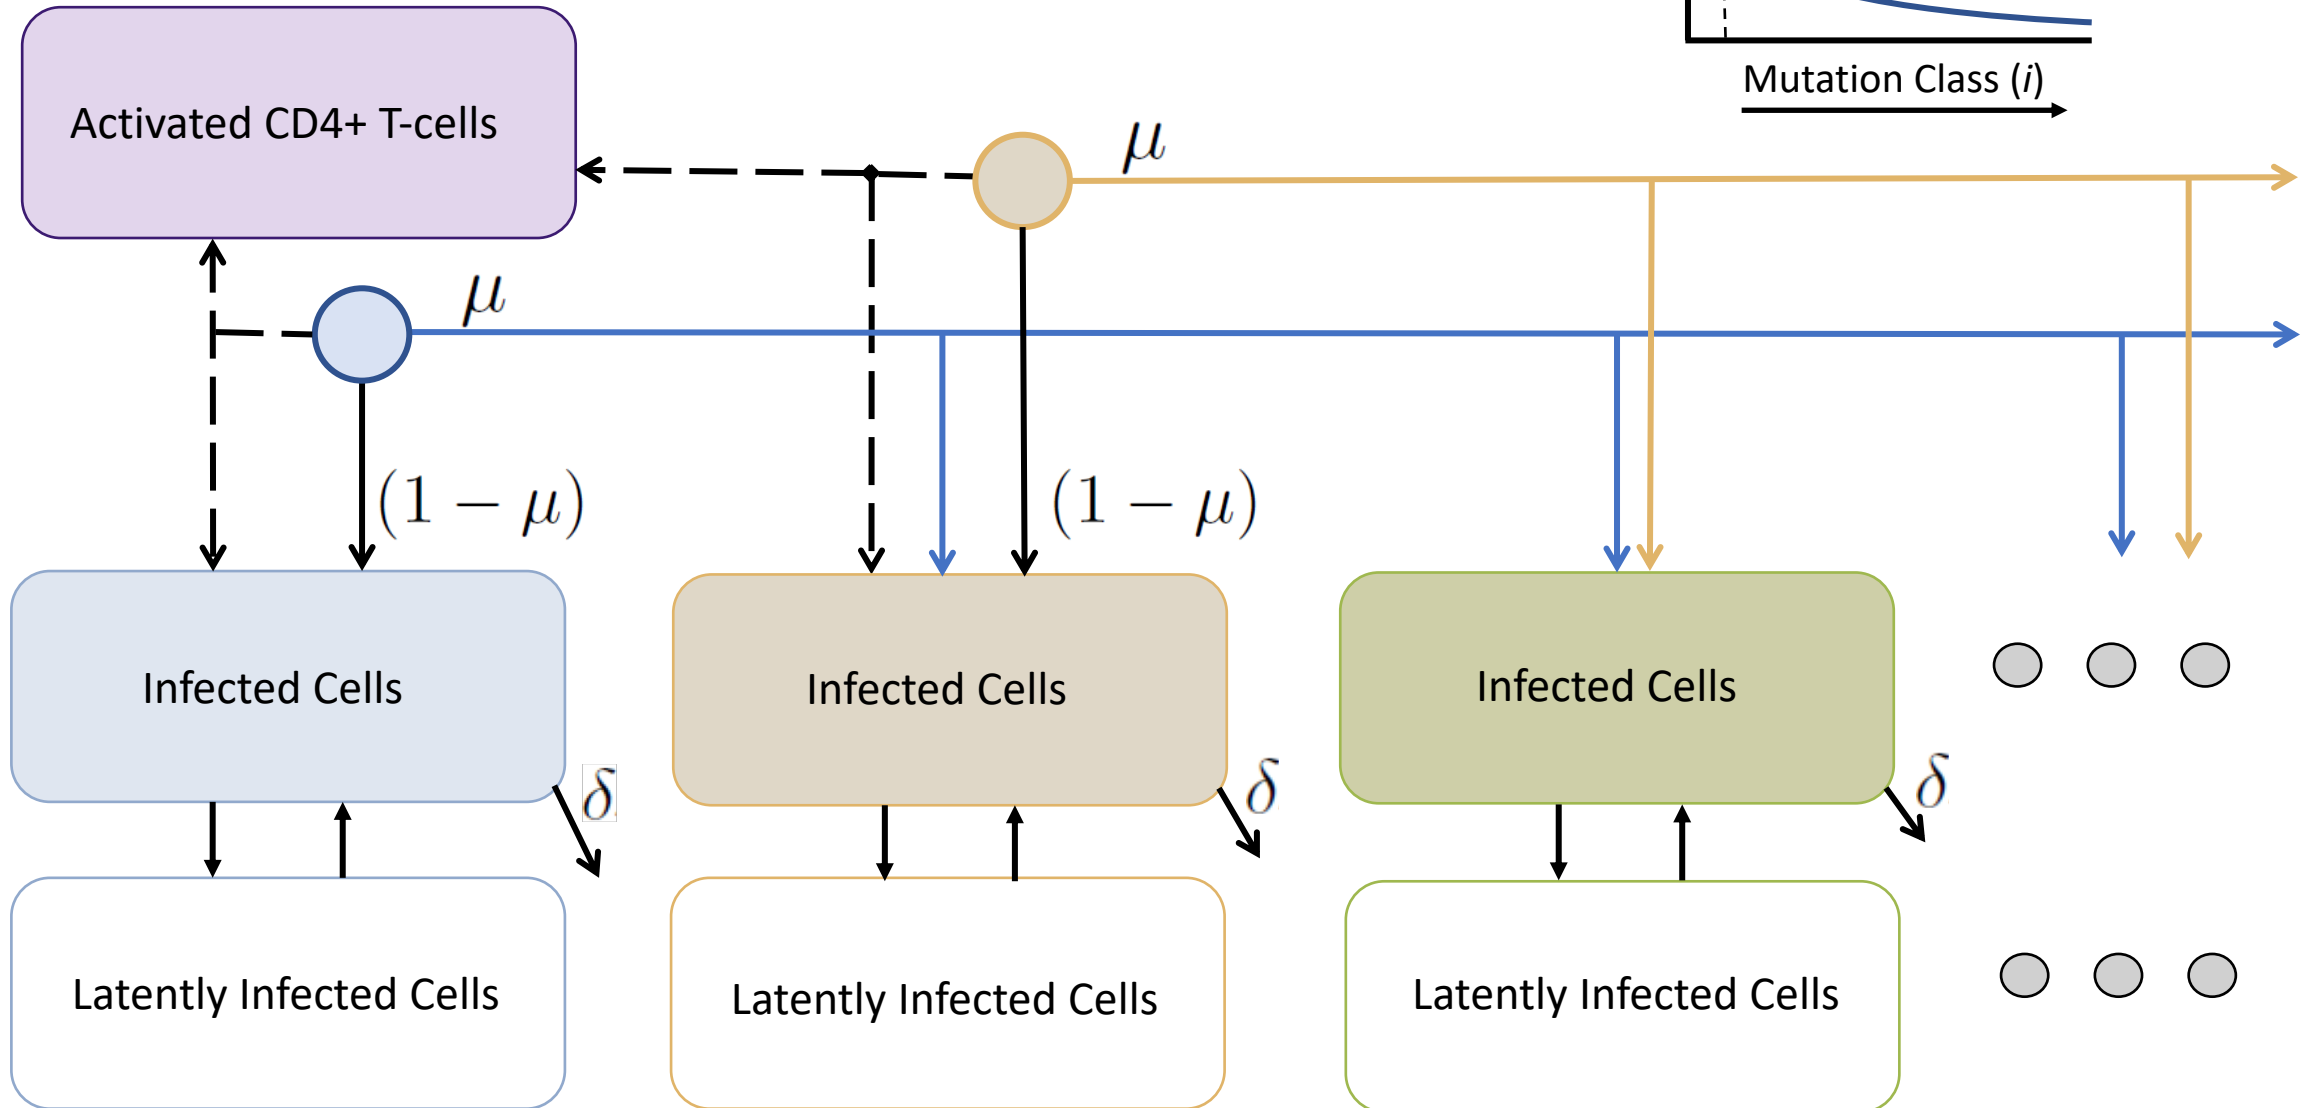

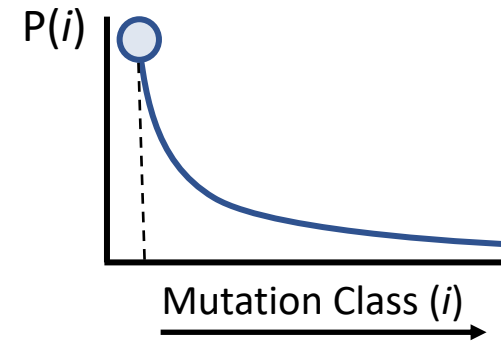

Deterministic host-cell-limited model of viral dynamics with fitness evolution and a latent reservoir

Between-host

Stochastic branching process model of disease transmission where the probability of founding a new infection and characteristics of the new infection are dependent on the within-host model

Methods: Within-host Dynamics

Methods: Fitness Evolution Within-host

$$\dot{x} = \lambda - dx - x \sum_i^n \beta y_i$$

μ

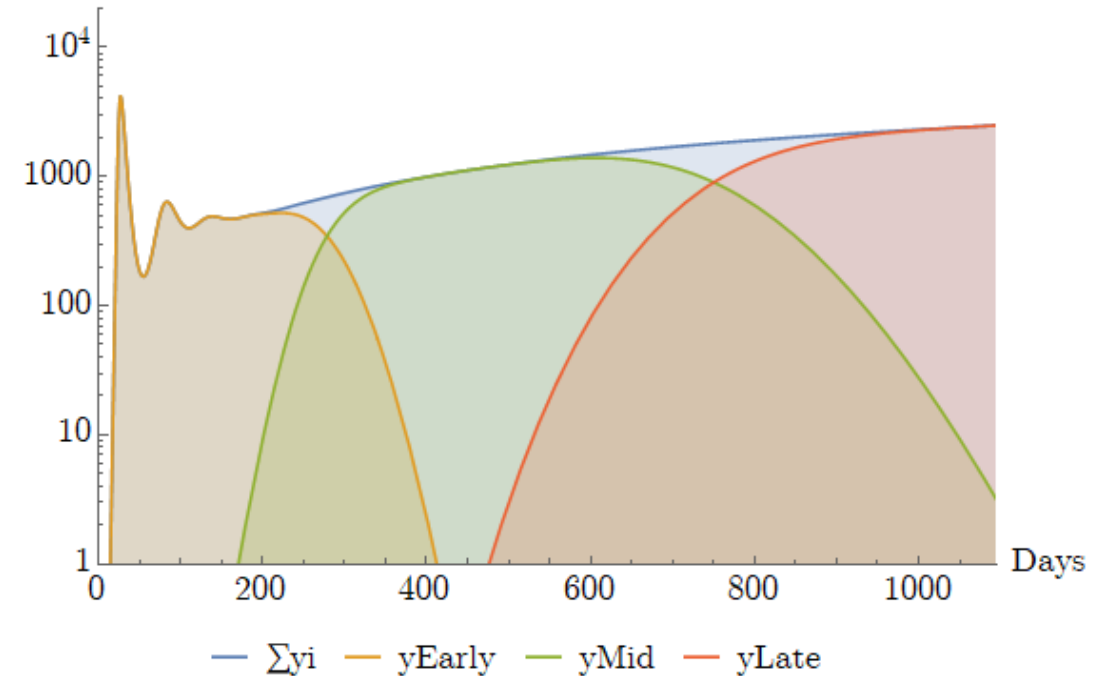

$$\dot{y}_i = x(1 - \mu)\beta y_i + x\mu \sum_{j=1}^n \beta K(i - j)y_j - \delta_i y_i - \gamma y_i + \alpha l_i$$

$$\dot{l}_i = \gamma y_i + (\rho - \alpha)l_i$$

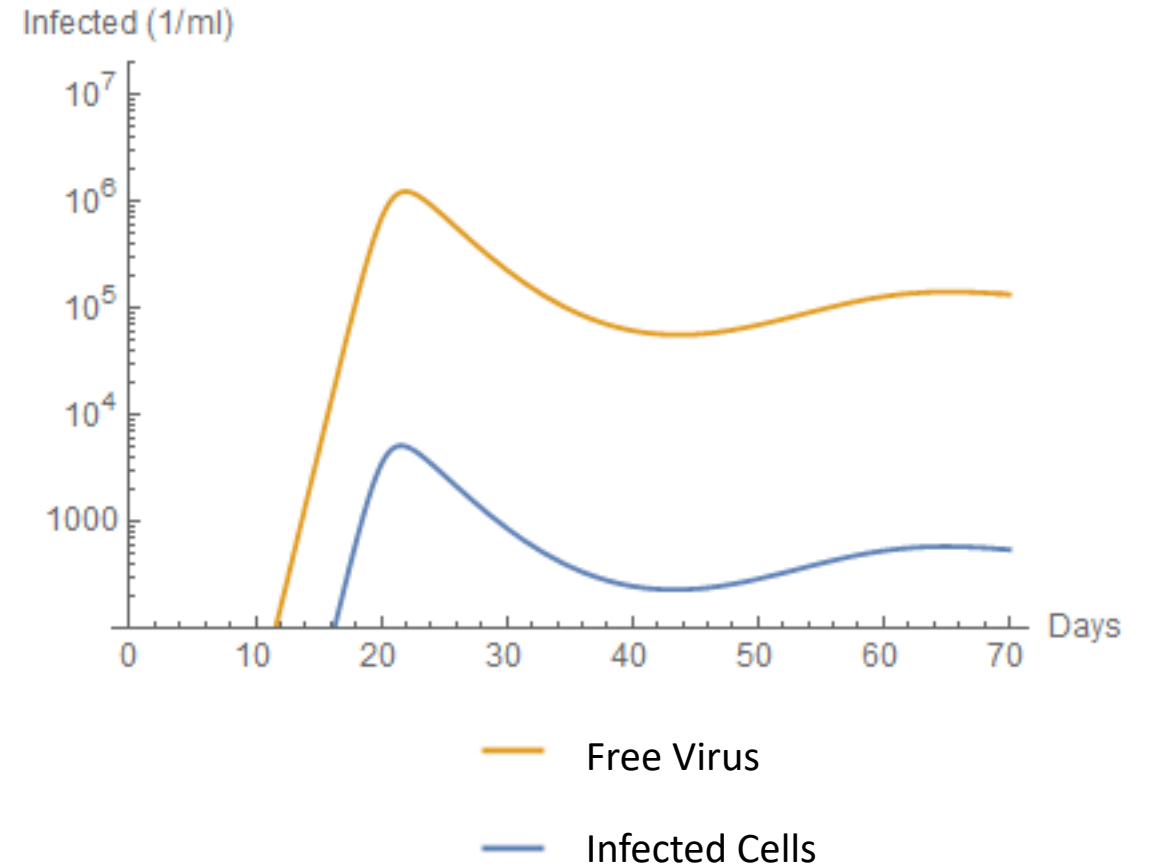

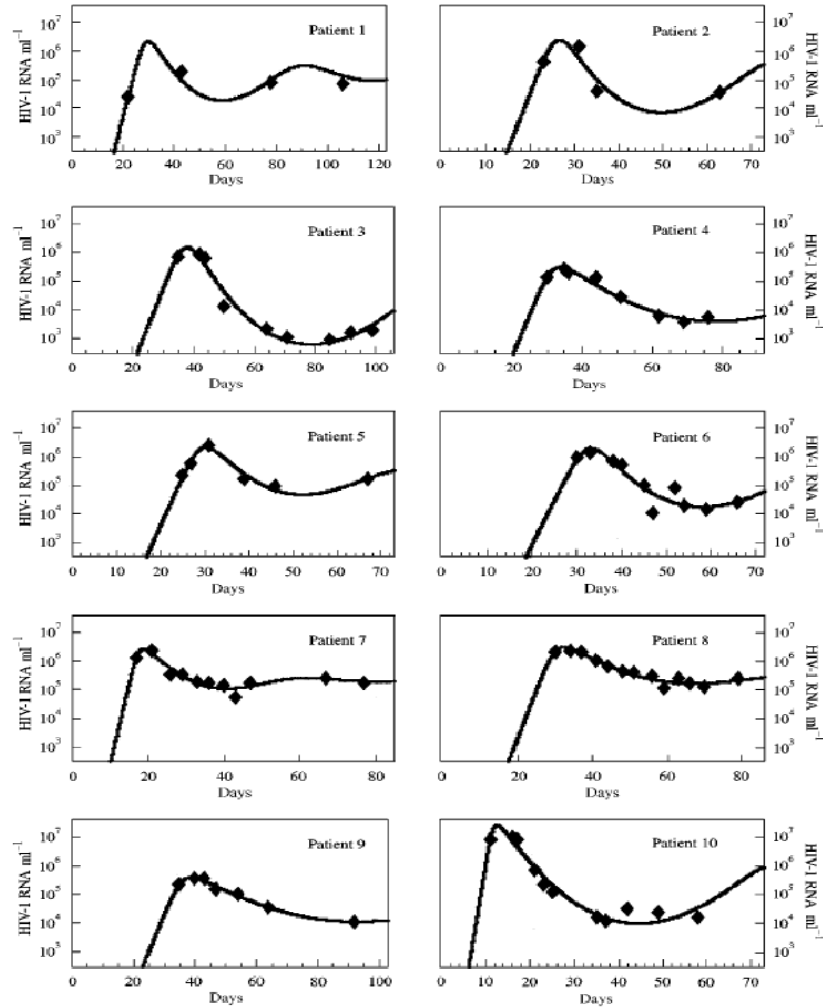

New fitness classes arise during viral replication

Increased fitness is included as a decreased removal rate of infected cells

Questions

Does allowing transmission fitness to evolve within-host without selection have the effect of slowing the observed rate of evolution over epidemic time?

Is the difference between within- and between host evolutionary rates sensitive to the size and composition of the bottleneck Inoculum

Results

Does allowing transmission fitness to evolve within-host without selection have the effect of slowing the observed rate of evolution over epidemic time?

- Changes are sensitive to the within-host viral distribution

Is the difference between within- and between host evolutionary rates sensitive to the size and composition of the bottleneck Inoculum

Results

Does allowing transmission fitness to evolve within-host without selection have the effect of slowing the observed rate of evolution over epidemic time?

- Changes are sensitive to the within-host viral distribution

Is the difference between within- and between host evolutionary rates sensitive to the size and composition of the bottleneck Inoculum

- Yes, the rates of evolution are sensitive to the size and composition of the transmission bottleneck Inoculum
- Our results **suggest** that bottleneck effects could amplify the changes in the observed rate of between-host evolution beyond that of the archival effects of the latent reservoir alone

Discussion

- Our modeling suggests the observed between-host rate of evolution is dependent on how well adapted the virus is to the host, and therefore slows over the course of the epidemic
- This dependence on how well adapted the virus to the host raises the question whether will allowing different hosts with distinct immune HLA types will reproduce the additional explanation for the difference in evolutionary rates, 'adapt and revert'

Introduction: Within-host

- Rapidly replicating virus
 - Immune escape
 - Host cell competition
- Approximately ten thousand nucleotides long
- Set-point viral load (SpVL) is a key correlate to virulence
- Has a long lived and evolutionarily stable latent reservoir

Fraser, C., Lythgoe, K, Leventhal, G, et. al. *Virulence and pathogenesis of HIV-1 infection: an evolutionary perspective.*, Science. **343**, 6177, pp. 1243727 (2014).
