## NLAFET: Parallel Numerical Linear Algebra for Future Extreme Scale Systems

L. Grigori and the NLAFET Consortium Team Umeå University, Inria, STFC, and University of Manchester

July 2017

Science \& Technology Facilities Council

The University of Manchester

## Towards Exascale High Performance Computing

Aim of the Horizon 2020 FETHPC call:
Attract projects that can achieve world-class extreme scale computing capabilities in platforms, technologies and applications

19 Research and Innovation Actions (RIA); 2 Coordination and Support Actions (CSA) Among those:

- Mathematics: NLAFET, ExaHYPE
- Algorithms: ExaFLOW, ExCAPE, ComPat, NLAFET, ExaHYPE

## Members of the NLAFET Consortium

- Umeå University, Sweden (UMU; Coordinator Bo Kågström; Lennart Edblom)
- The University of Manchester, UK (UNIMAN; Jack Dongarra; Nick Higham)
- Institute National de Recherche en Informatique et en Automatique, France (INRIA; Laura Grigori)
- Science and Technology Facilities Council, UK (STFC; Iain Duff)

Collaborating partners:

- Innovative Computing Laboratory (ICL), UT Knoxville
- James Demmel, UC Berkeley
- Individual researchers (academia and vendors)

Key European players with recognized leadership, proven expertise, experience, and skills across the scientific areas of NLAFET!

## NLAFET—Aim and Main Research Objectives

Aim: Enable a radical improvement in the performance and scalability of a wide range of real-world applications relying on linear algebra software for future extreme-scale systems.

- Development of novel architecture-aware algorithms that expose as much parallelism as possible, exploit heterogeneity, avoid communication bottlenecks, respond to escalating fault rates, and help meet emerging power constraints
- Exploration of advanced scheduling strategies and runtime systems focusing on the extreme scale and strong scalability in multi/many-core and hybrid environments
- Design and evaluation of novel strategies and software support for both offline and online auto-tuning
- Results will appear in the open source NLAFET software library

## NLAFET Work Package Overview

- WP1: Management and coordination (start M1)
- WP5: Challenging applications-a selection (start M13) Materials science, power systems, study of energy solutions, and data analysis in astrophysics
- WP7: Dissemination and community outreach (start M1) Research and validation results; stakeholder communities

## Research focus-Critical set of NLA operations

- WP2: Dense linear systems and eigenvalue problem solvers
- WP3: Direct solution of sparse linear systems
- WP4: Communication-optimal algorithms for iterative methods
- WP6: Cross-cutting issues (All four start M1)

WP2, WP3 and WP4: research into extreme-scale parallel algorithms
WP6: research into methods for solving common cross-cutting issues

## WP2, WP3 and WP4 at a glance!

- Linear Systems Solvers
- Hybrid (Batched) BLAS
- Eigenvalue Problem Solvers
- Singular Value Decomposition Algorithms
- Lower Bounds on Communication for Sparse Matrices
- Direct Methods for (Near-)Symmetric Systems
- Direct Methods for Highly Unsymmetric Systems
- Hybrid Direct-Iterative Methods
- Computational Kernels for Preconditioned Iterative Methods
- Iterative Methods: use $t$ vectors per it, nearest-neighbor comm
- Preconditioners: multi-level, communication reducing

## Krylov subspace methods

Solve $A x=b$ by finding a sequence $x_{1}, x_{2}, \ldots, x_{k}$ that minimizes some measure of error over the corresponding spaces

$$
x_{0}+\mathcal{K}_{i}\left(A, r_{0}\right), \quad i=1, \ldots, k
$$

They are defined by two conditions:

1. Subspace condition: $x_{k} \in x_{0}+\mathcal{K}_{k}\left(A, r_{0}\right)$
2. Petrov-Galerkin condition: $r_{k} \perp \mathscr{L}_{k}$

$$
\Longleftrightarrow\left(r_{k}\right)^{t} y=0, \quad \forall y \in \mathscr{L}_{k}
$$

where

- $x_{0}$ is the initial iterate, $r_{0}$ is the initial residual,
- $\mathcal{K}_{k}\left(A, r_{0}\right)=\operatorname{span}\left\{r_{0}, A r_{0}, A^{2} r_{0}, \ldots, A^{k-1} r_{0}\right\}$ is the Krylov subspace of dimension $k$,
- $\mathscr{L}_{k}$ is a well-defined subspace of dimension $k$.

## Challenge in getting efficient and scalable solvers

- Solve $A x=b$ by using a Krylov subspace method: find $x_{k}$ from $x_{0}+\mathcal{K}_{k}\left(A, r_{0}\right)$ where

$$
\mathcal{K}_{k}\left(A, r_{0}\right)=\operatorname{span}\left\{r_{0}, A r_{0}, A^{2} r_{0}, \ldots, A^{k-1} r_{0}\right\}
$$

such that the Petrov-Galerkin condition $b-A x_{k} \perp \mathscr{L}_{k}$ is satisfied.

Typically, each iteration requires

- Sparse matrix vector product
$\rightarrow$ point-to-point communication Dot products for orthogonalization

## Challenge in getting efficient and scalable solvers

- Solve $A x=b$ by using a Krylov subspace method: find $x_{k}$ from $x_{0}+\mathcal{K}_{k}\left(A, r_{0}\right)$ where

$$
\mathcal{K}_{k}\left(A, r_{0}\right)=\operatorname{span}\left\{r_{0}, A r_{0}, A^{2} r_{0}, \ldots, A^{k-1} r_{0}\right\}
$$

such that the Petrov-Galerkin condition $b-A x_{k} \perp \mathscr{L}_{k}$ is satisfied.

Typically, each iteration requires

- Sparse matrix vector product $\rightarrow$ point-to-point communication
- Dot products for orthogonalization $\rightarrow$ global communication

## Ways to improve performance

## Typical approaches

- Improve the performance of sparse matrix-vector product
- Improve the performance of collective communication

NLAFET approach

- Change numerics - reformulate or introduce Krylov subspace algorithms to:
$\square$ reduce communication
$\square$ increase arithmetic intensity - compute sparse matrix-set of vectors product
- Use preconditioners to decrease the number of iterations till convergence

## Enlarged Krylov methods

- Partition the matrix into $t$ domains
- Split the residual $r_{0}$ into $t$ vectors corresponding to the $t$ domains,

$r_{0} \rightarrow T\left(r_{0}\right)=\left[\begin{array}{cccc}* & 0 & & 0 \\ \vdots & \vdots & & \vdots \\ * & 0 & & 0 \\ 0 & * & & 0 \\ \vdots & \vdots & & \vdots \\ 0 & * & & 0 \\ & & \ddots & \\ 0 & 0 & & * \\ \vdots & \vdots & & \vdots \\ 0 & 0 & & *\end{array}\right]$
- Generate $t$ new basis vectors, obtain an enlarged Krylov subspace

$$
\mathcal{K}_{t, k}\left(A, r_{0}\right)=\operatorname{span}\left\{T\left(r_{0}\right), A T\left(r_{0}\right), A^{2} T(r 0), \ldots, A^{k-1} T\left(r_{0}\right)\right\}
$$

- Search for the solution of $A x=b$ in $\mathcal{K}_{t, k}\left(A, r_{0}\right)$
- [Grigori and Moufawad, 2014, Grigori and Tissot, 2017, Daas et al., 2017]

## Properties of enlarged Krylov subspaces

- The Krylov subspace $\mathcal{K}_{k}\left(A, r_{0}\right)$ is a subset of the enlarged one

$$
\mathcal{K}_{k}\left(A, r_{0}\right) \subset \mathcal{K}_{t, k}\left(A, r_{0}\right)
$$

- For all $k<k_{\text {max }}$ the dimensions of $\mathcal{K}_{t, k}$ and $\mathcal{K}_{t, k+1}$ are stricltly increasing by some number $i_{k}$ and $i_{k+1}$ respectively, where

$$
t \geq i_{k} \geq i_{k+1} \geq 1
$$

- The enlarged subspaces are increasing subspaces, yet bounded.
$\mathcal{K}_{t, 1}\left(A, r_{0}\right) \subsetneq \ldots \subsetneq \mathcal{K}_{t, k_{\max }-1}\left(A, r_{0}\right) \subsetneq \mathcal{K}_{t, k_{\max }}\left(A, r_{0}\right)=\mathcal{K}_{t, k_{\max }+q}\left(A, r_{0}\right), \forall q>0$
- The solution of the system $A x=b$ belongs to the subspace $x_{0}+\mathcal{K}_{t, k_{\max }}$.

## Enlarged Krylov subspace methods based on CG

Defined by the subspace $\mathcal{K}_{t, k}$ and the following two conditions:

1. Subspace condition: $x_{k} \in x_{0}+\mathcal{K}_{t, k}$
2. Orthogonality condition: $r_{k} \perp \mathcal{K}_{t, k}$

- At each iteration, the new approximate solution $x_{k}$ is found by minimizing $\phi(x)=\frac{1}{2}(x)^{t} A x-b^{t} x$ over $x_{0}+\mathcal{K}_{t, k}$ :

$$
\phi\left(x_{k}\right)=\min \left\{\phi(x), \forall x \in x_{0}+\mathcal{K}_{t, k}\left(A, r_{0}\right)\right\}
$$

- Can be seen as a particular case of a block Krylov method:
$\square A X=S(b)$ such that $S(b) \cdot$ ones $(t, 1)=b, R_{0}=A X_{0}-S(b)$
$\square$ Orthogonality condition involves the block residual $R_{k} \perp \mathcal{K}_{t, k}$

## Convergence analysis

## Given

- $A$ is an SPD matrix, $x^{*}$ is the solution of $A x=b$
- $\left\|\bar{e}_{k}\right\|_{A}=\left\|x^{*}-\bar{x}_{k}\right\|_{A}$ is the $k^{\text {th }}$ error of CG
- $\left\|e_{k}\right\|_{A}=\left\|x^{*}-x_{k}\right\|_{A}$ is the $k^{t h}$ error of enlarged methods
- CG converges in $\bar{K}$ iterations

## Result

Enlarged Krylov methods converge in $K$ iterations, where $K \leq \bar{K} \leq n$.

$$
\left\|e_{k}\right\|_{A}=\left\|x^{*}-x_{k}\right\|_{A} \leq\left\|\bar{e}_{k}\right\|_{A}
$$

## Classical CG vs. Enlarged CG

## BLAS 3 operations

\# messages per iteration
$\mathrm{O}(\log \mathrm{P})$ from $\mathrm{BCGS}+\mathrm{A}$-ortho + O(1) from SpMsetV

## Dynamic reduction of search directions

- If $R_{k-1}$ becomes rank deficient,

$$
\begin{aligned}
R_{k-1} v=0 & \Longrightarrow \quad R_{i} v=0, \forall i \geq k \\
& \Longrightarrow X_{i-1} v=X^{*} v
\end{aligned}
$$

- Monitor the rank of $\alpha_{k}$ instead of $R_{k-1}$ to select search directions

$$
\alpha_{k}=P_{k}^{T} R_{k-1} \approx U_{k}^{(1)} \sigma_{k}^{(1)} W_{k}^{(1)}
$$

- The new search directions are given by the relation:

$$
\begin{aligned}
X_{k}= & X_{k-1}+P_{k} \alpha_{k}=X_{k-1}+\left(P_{k} U_{k}^{(1)}\right)\left(\Sigma_{k}^{(1)} V_{k}^{(1)^{t}}\right) \\
= & X_{k-1}+P_{k}^{(1)} \alpha_{k}^{(1)}, \\
& X_{k}, R_{k} \in \mathbb{R}^{n \times t}, \alpha_{k}^{(1)} \in \mathbb{R}^{\operatorname{rank}\left(\alpha_{k}\right) \times t}, P_{k}^{(1)} \in \mathbb{R}^{n \times \operatorname{rank}\left(\alpha_{k}\right)}
\end{aligned}
$$

- Idea adapted from Robbé and Sadkane (2006)

## Test cases: boundary value problem

3D Skyscraper Problem - SKY3D

$$
\begin{aligned}
-\operatorname{div}(\kappa(x) \nabla u) & =f \text { in } \Omega \\
u & =0 \text { on } \partial \Omega_{D} \\
\frac{\partial u}{\partial n} & =0 \text { on } \partial \Omega_{N}
\end{aligned}
$$

discretized on a 3D grid, where
$\kappa(x)=\left\{\begin{array}{l}10^{3} *\left(\left[10 * x_{2}\right]+1\right), \text { if }\left[10 * x_{i}\right]=\operatorname{Omod}(2), i=1,2,3, \\ 1, \\ \text { otherwise } .\end{array}\right.$
3D Anisotropic layers - ANI3D

- $\Omega$ divided into 10 layers parallel to $z=0$, of size 0.1
- in each layer, the coefficients are constants ( $\kappa_{x}$ equal to $1,10^{2}$ or $10^{4}$, $\left.\kappa_{y}=10 \kappa_{x}, \kappa_{z}=1000 \kappa_{x}\right)$.

## Test cases (contd)

## Linear elasticity 3D problem

$$
\begin{aligned}
\operatorname{div}(\sigma(u))+f & =0 & & \text { on } \Omega \\
u & =u_{D} & & \text { on } \partial \Omega_{D} \\
\sigma(u) \cdot n & =g & & \text { on } \partial \Omega_{N}
\end{aligned}
$$

Figure: The distribution of Young's modulus

- $u \in \mathbb{R}^{d}$ is the unknown displacement field, $f$ is some body force.
- Young's modulus $E$ and Poisson's ratio $\nu$ take two values, $\left(E_{1}, \nu_{1}\right)=\left(2 \cdot 10^{11}, 0.25\right)$, and $\left(E_{2}, \nu_{2}\right)=\left(10^{7}, 0.45\right)$.
- Cauchy stress tensor $\sigma(u)$ is given by Hooke's law, defined by $E$ and $\nu$.

## Enlarged CG: numerical results

- Block Jacobi preconditioner (1024 blocks)
- Stopping criterion $10^{-6}$
- Initial block size 32
- BRRHS-CG (Nikishin and Yeremin, 1995): block method with $t-1$ random rhs

|  |  | PCG | BRRHS-CG |  | ECG |  |
| :--- | :---: | :---: | :---: | :---: | :---: | :---: |
|  | red. | iter | iter | $\operatorname{dim}\left(\mathcal{K}_{t, k}\right)$ | iter | $\operatorname{dim}\left(\mathcal{K}_{t, k}\right)$ |
| SKY2D | $\times$ | 655 | 61 | 1952 | 57 | 1824 |
|  | $\checkmark$ | 655 | 61 | 1739 | 59 | 1546 |
| Ela3D100 | $\times$ | 955 | 102 | 3264 | 109 | 3488 |
|  | $\checkmark$ | 955 | 102 | 3093 | 116 | 2384 |
| Ela2D200 | $\times$ | 4551 | 255 | 8160 | 253 | 8096 |
|  | $\checkmark$ | 4551 | 258 | 7331 | 266 | 6553 |

## Enlarged CG: parallel performance

- MeSU (UPMC cluster) Intel Xeon E5-2670v3 (12 cores), 24 cores per node
- Comparison with PETSc 3.7.4

| Method | iter | time (s) | time/iter |
| :---: | :---: | :---: | :---: |
| ECG(12) | 318 | 1.3 | $4.1 \times 10^{-3}$ |
| PETSc | 5198 | 3.3 | $6.3 \times 10^{-4}$ |

Ela400, nproc $=48$

Ela400

## Detailed profiling (source slide O. Tissot)

- Ela400 on 96 cores
- Orthodir ECG(12)

- Around $50 \%$ of the time spent in applying the preconditioner
- Around $30 \%$ of the time spent in Sparse Matrix-Matrix

| Method | iter | time (s) | time/iter |
| :---: | :---: | :---: | :---: |
| ECG(12) | 318 | 1.3 | $4.1 \times 10^{-3}$ |
| PETSc | 5198 | 3.3 | $6.3 \times 10^{-4}$ |

Table: Comparison with PETSc PCG. PETSc iteration is 6.5 times faster than ECG(12) one. MKL-Pardiso has a strange behaviour with multiple rhs $n$ our experiments: 1 rhs solve is 3 times faster than 2 rhs solve.

## Conclusions

- Enlarged CG converges faster than classic CG on our test matrices
$\square$ number of global reductions is reduced significantly
$\square$ arithmetic intensity is increased
- Prototype code in C and MPI available
- Implement the block size reduction, tuning, and optimize the code
- Code will be available in november 2017
